Nidhi Riju
Eisenhower Matrix

	Urgent	***Not Urgent***
Important	**Do:** ● Create and store multiple local user profiles (which would include their comfort thresholds) ● Fetch current West Lafayette weather (specifically the temperature, precipitation, and wind) ● Compare the weather conditions against the user's thresholds ● Output the recommendation with a short reason ● Selecting which profile to use when starting up the program	**Schedule:** ● Edit and deleting existing profiles ● Weighted scoring (if rain matters more than the wind) instead of a simple pass/fail ● Commute distance and/or walking-time for the route ● Error messages (so the user knows why the code is not working - like if the API is down) ● Colored terminal output (green for walking, red for taking the bus) ● A class schedule file that would auto recommend for each class what to do
Not Important	**Delegate:** ● Use Java's HttpClient ● Open-Meteo weather API ● Scanner for input reader	**Delete** ● Mobile app ● Real-time bus tracking ● Machine learning that would learn the user's actual tolerance from past choices ● Push notifications set for each morning (that would be based on the class schedule) ● Syncing profiles across multiple devices ● Campus map with walking routes ● Gamify (compare amount walked with friends)
